

EVIDENCE-BASED DECISION MAKING AT HEALTHY WATERS: RAINFALL FORECASTING SKILL ASSESSMENT FRAMEWORK

L. Sutherland-Stacey, J. Nicol & B. Viso (Weather Radar New Zealand Limited)

F. MacDonald, K Fordham & N. Brown (Auckland Council Healthy Waters Department)

T. Carey-Smith (National Institute of Water and Atmosphere- NIWA)

May 2023

Friday 27 Jan PM Rain, pressure and wind

+HRE

Motivation

WEATHER DATA

It's the core of everything we do

**EVIDENCE
BASED
DECISIONS**

1. Understanding currently available Weather Data
2. Understanding what this means for decision making

OBSERVATIONS

Measurements.

FORECASTS

Not Measurements.
Models.

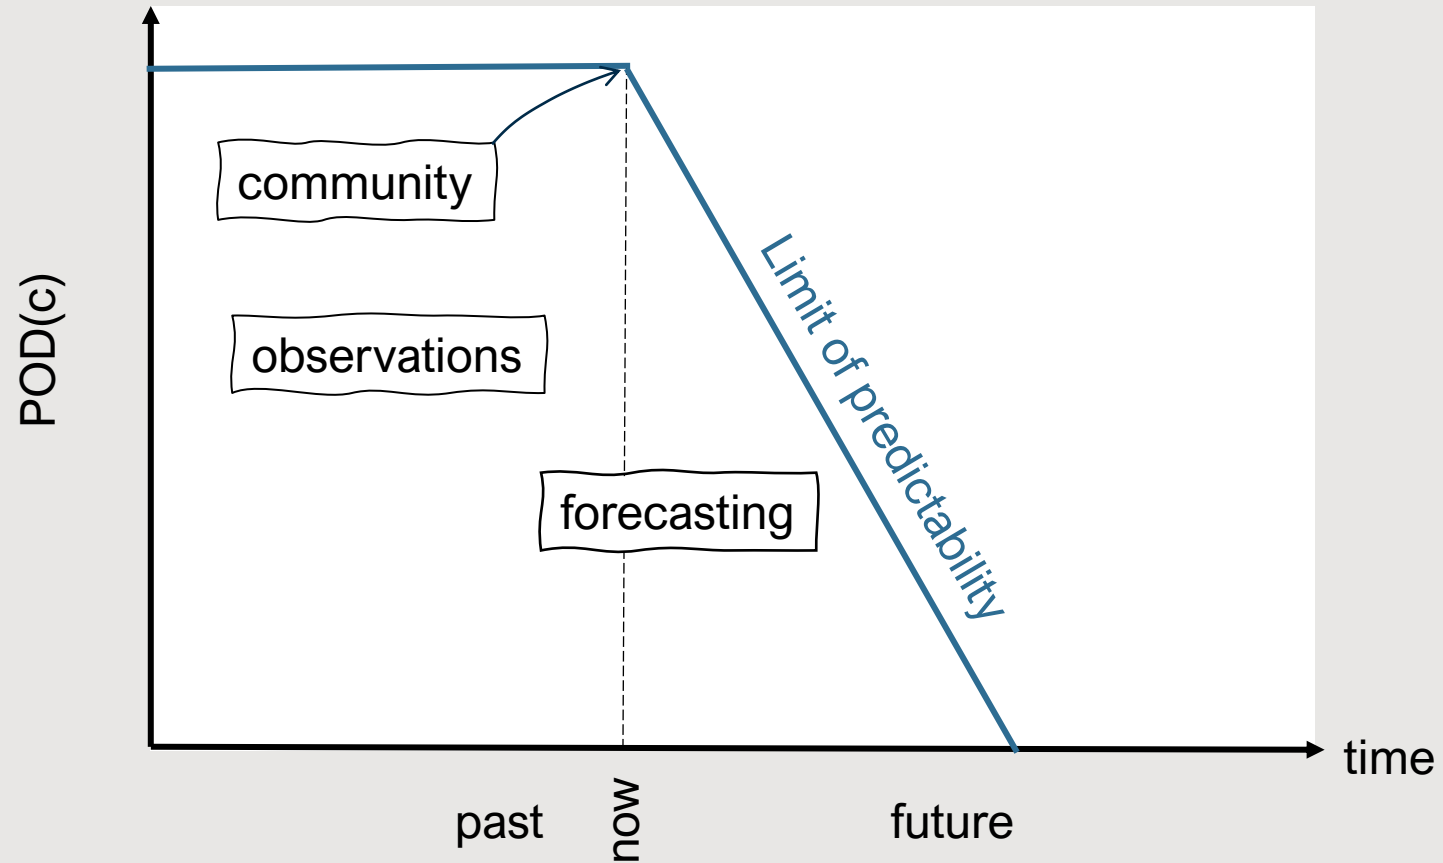

DECISION MAKING PROCESSES

- What is “Weather Data”?
- Having decided what it is, how can we estimate our confidence in it?
- Can we make good, or better, decisions about managing risk, and about investments?

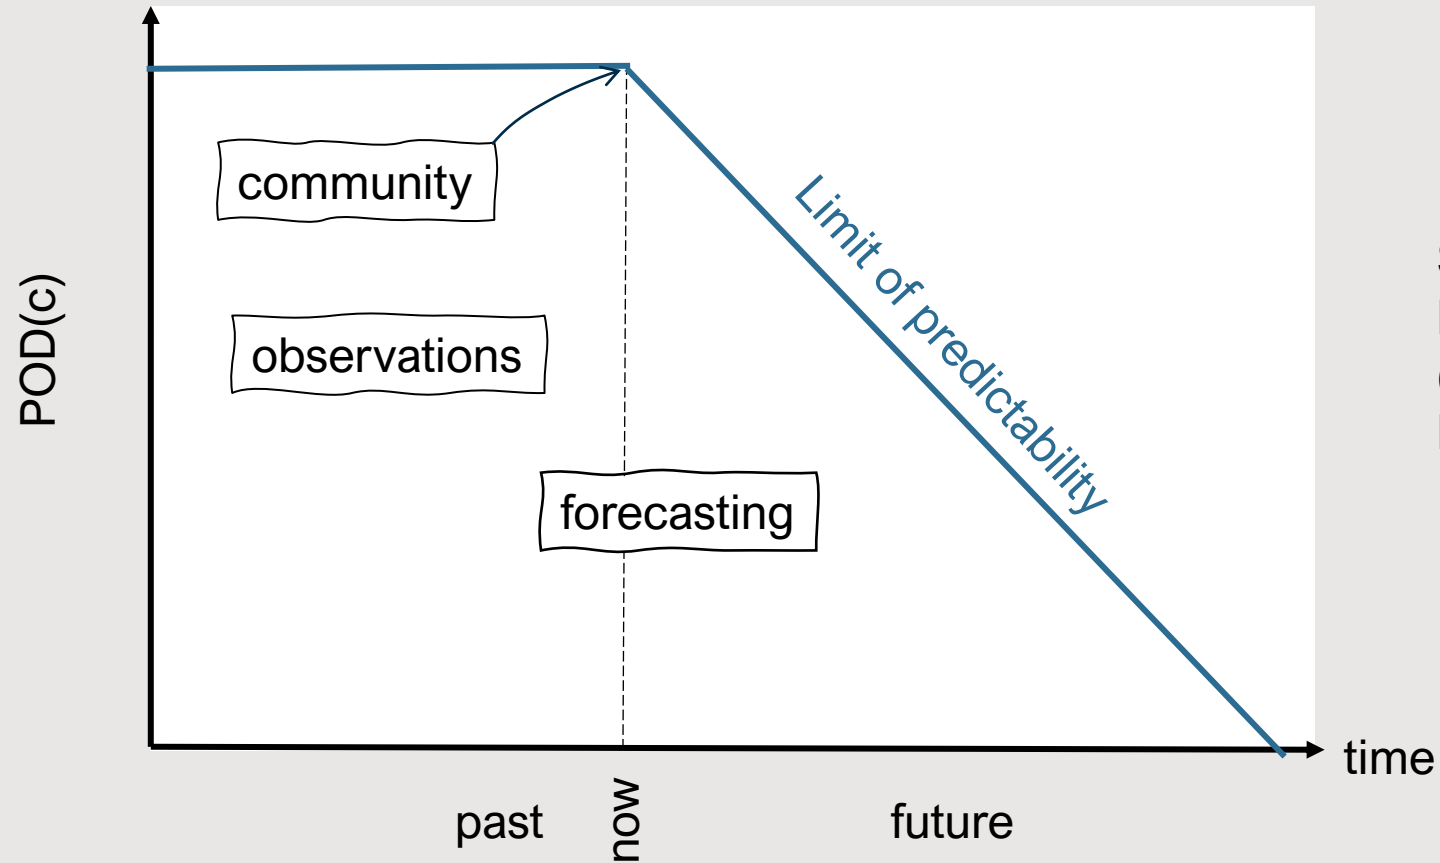

Predictability of the Atmospheric State

after Austin et al 1987

Predictability of the Atmospheric State

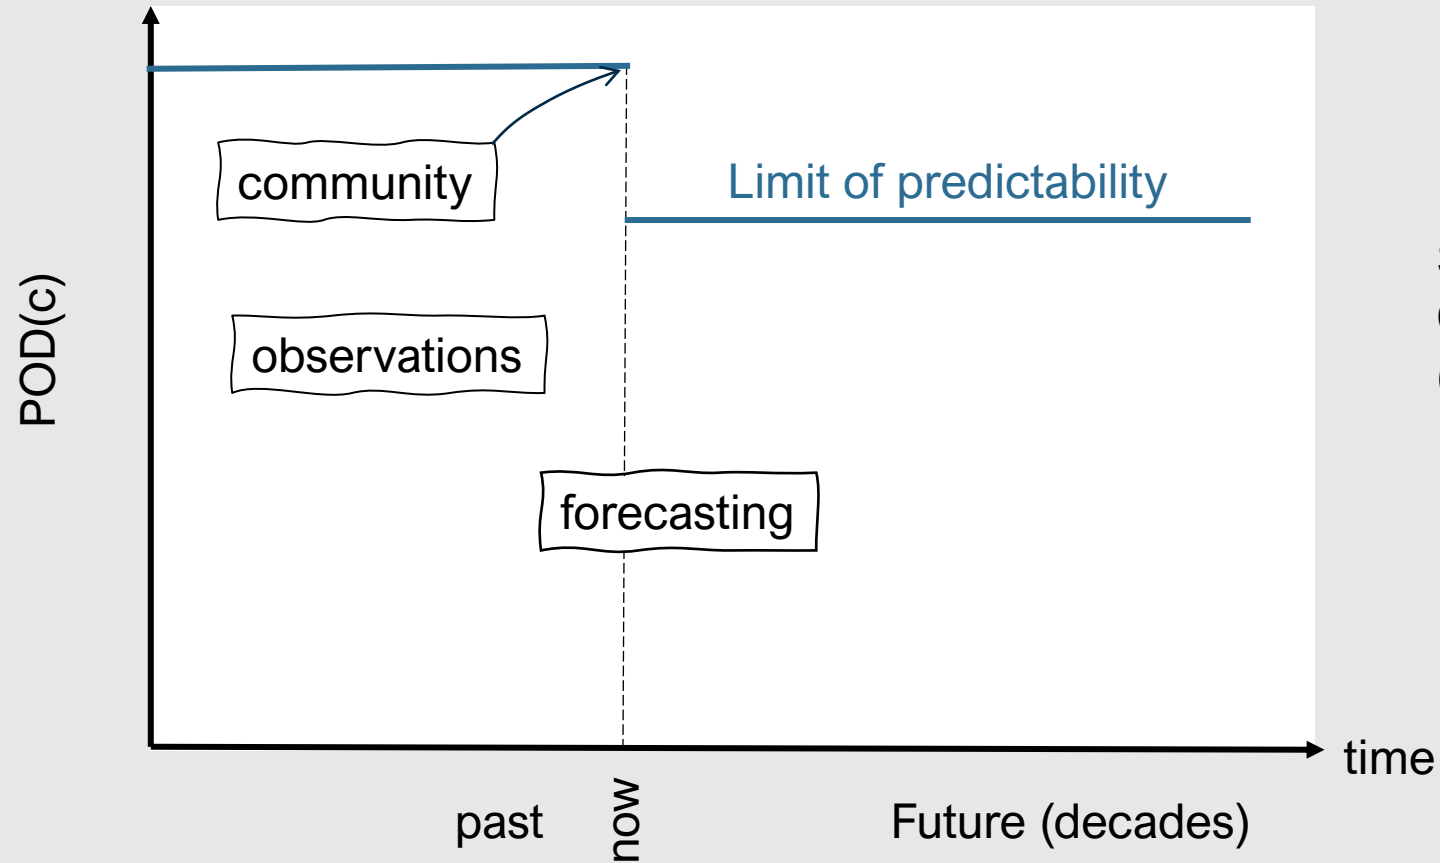

Solutions:
Less precise language
(timing, location, confidence)
Larger Scales

after Austin et al 1987

Predictability of the Atmospheric State

Solutions:
Climate Scales
(Planning Rules)

after Austin et al 1987

Weather Data systems at Healthy Waters

Observations (Now)

In-situ and remote instrument observations of rainfall (rain gauges, radar etc.)

Event total rainfall (2023/01/27 00:00 to 2023/01/28 00:00 (NZDT))

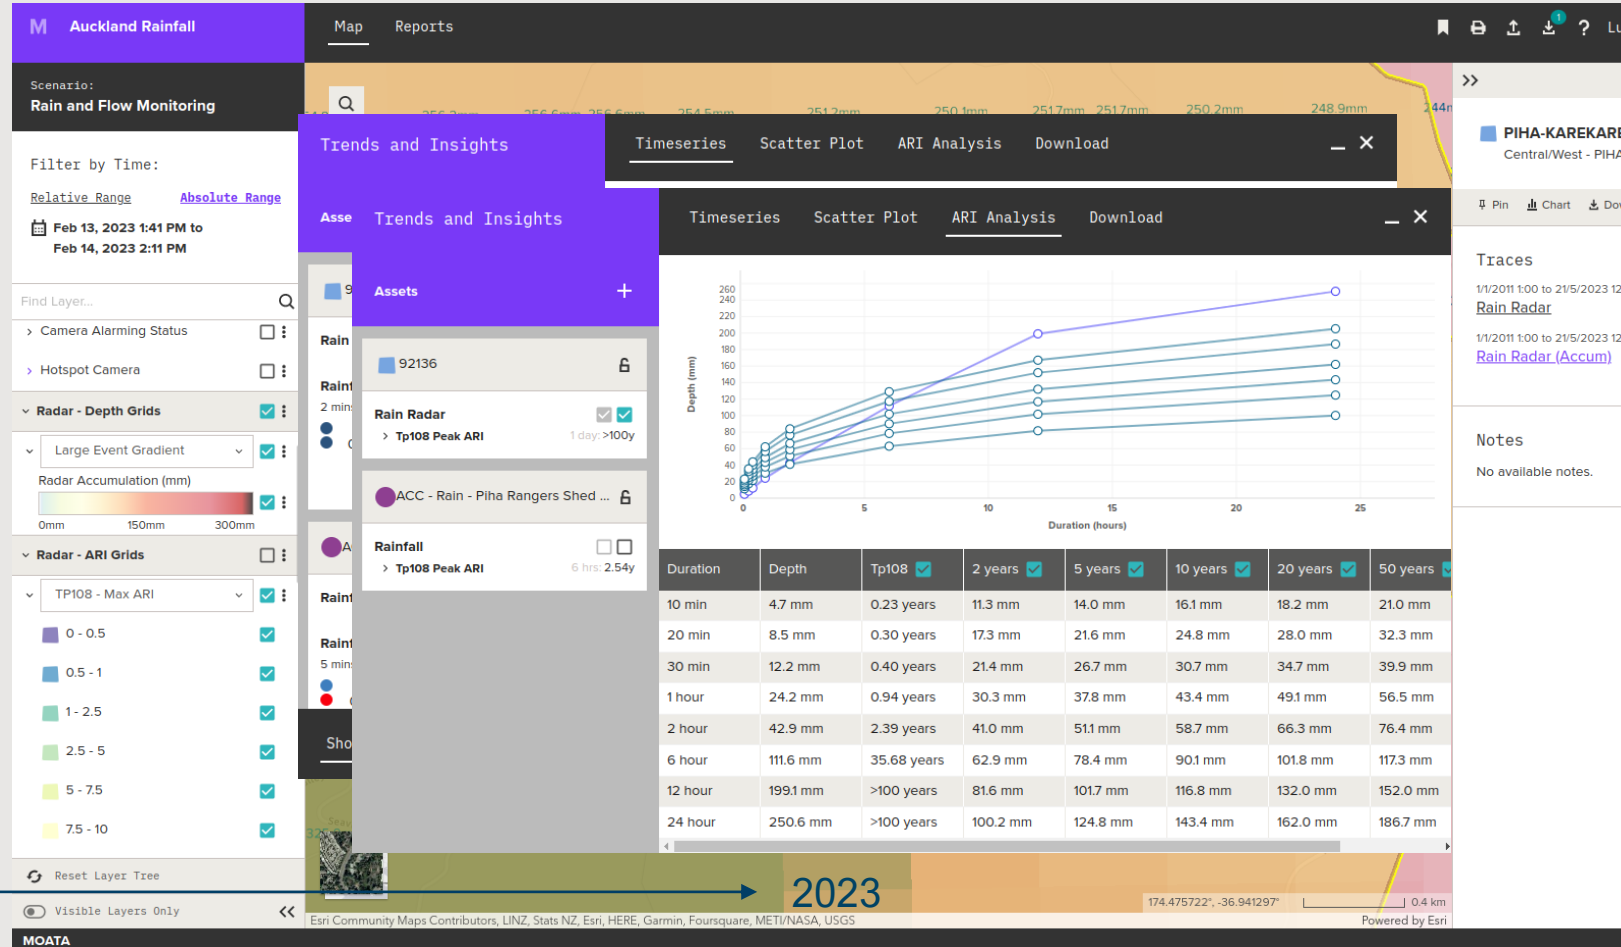

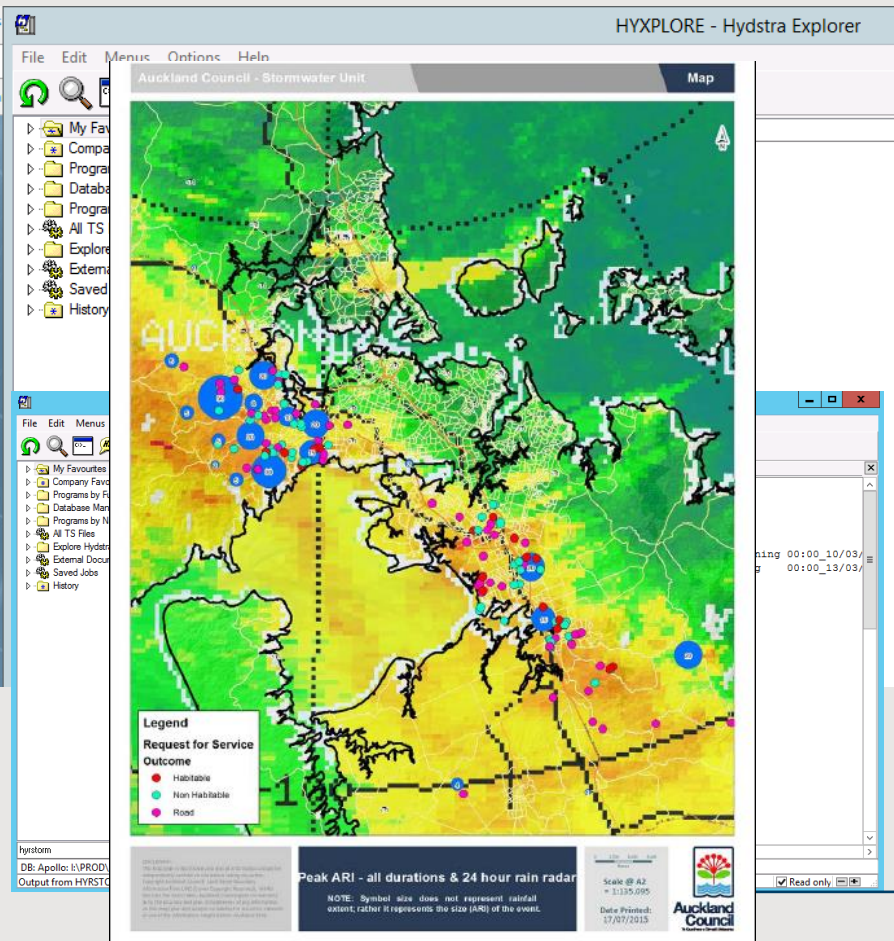

Radar and Gauge are combined in a Rainfall Analysis System (RAS)

Weather Data systems at Healthy Waters

Observations (Now)

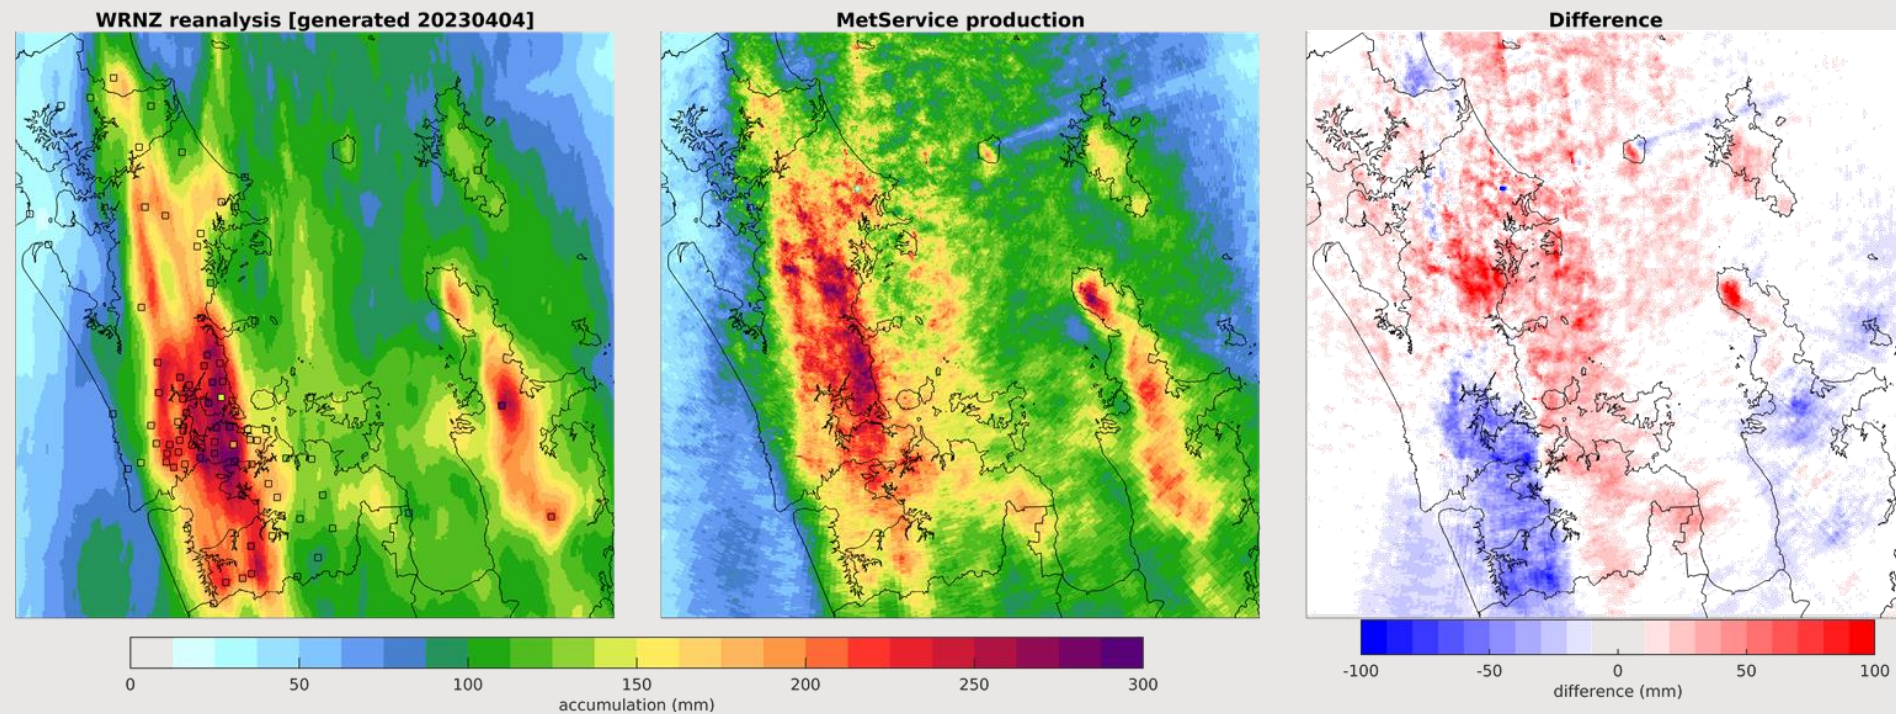

The RAINFALL ANALYSIS SYSTEM required a significant investment.

RIGOUR

- Quality level of the MetService radar-derived rainfall analysis confounds any attempt to use the data in engineering / EWS applications .
- (discussed in our earlier Stormwater Conference talks!)
- Contemporaneous example:

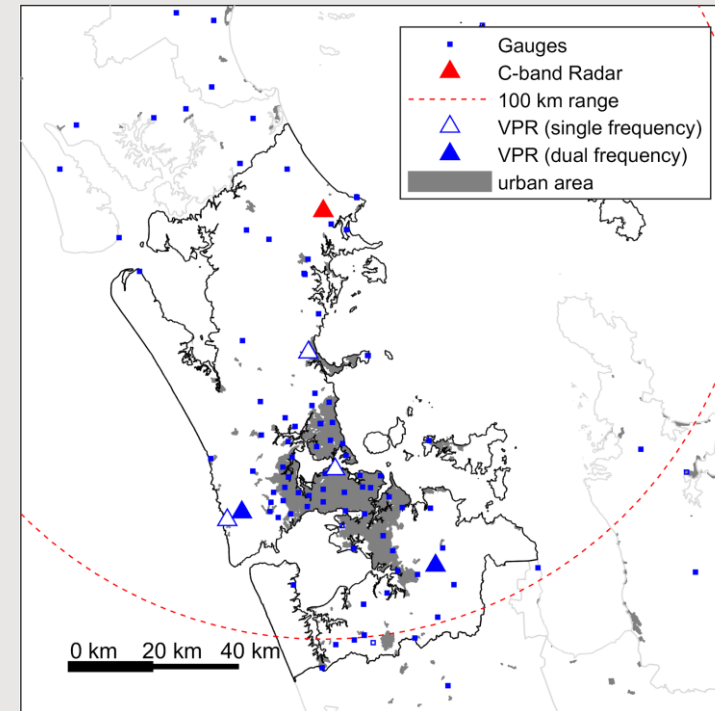

Event total rainfall (2023/01/27 00:00 to 2023/01/28 00:00 (NZDT))

The RAINFALL ANALYSIS SYSTEM required a significant investment.

PATHWAYS TO IMPROVEMENTS

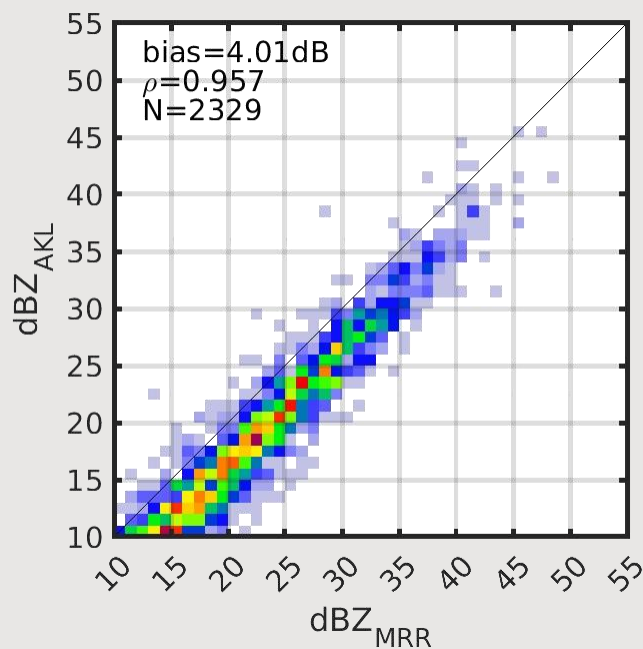

- An investment in science was required to realise a useable Weather Data type from radar

The RAINFALL ANALYSIS SYSTEM required a significant investment.

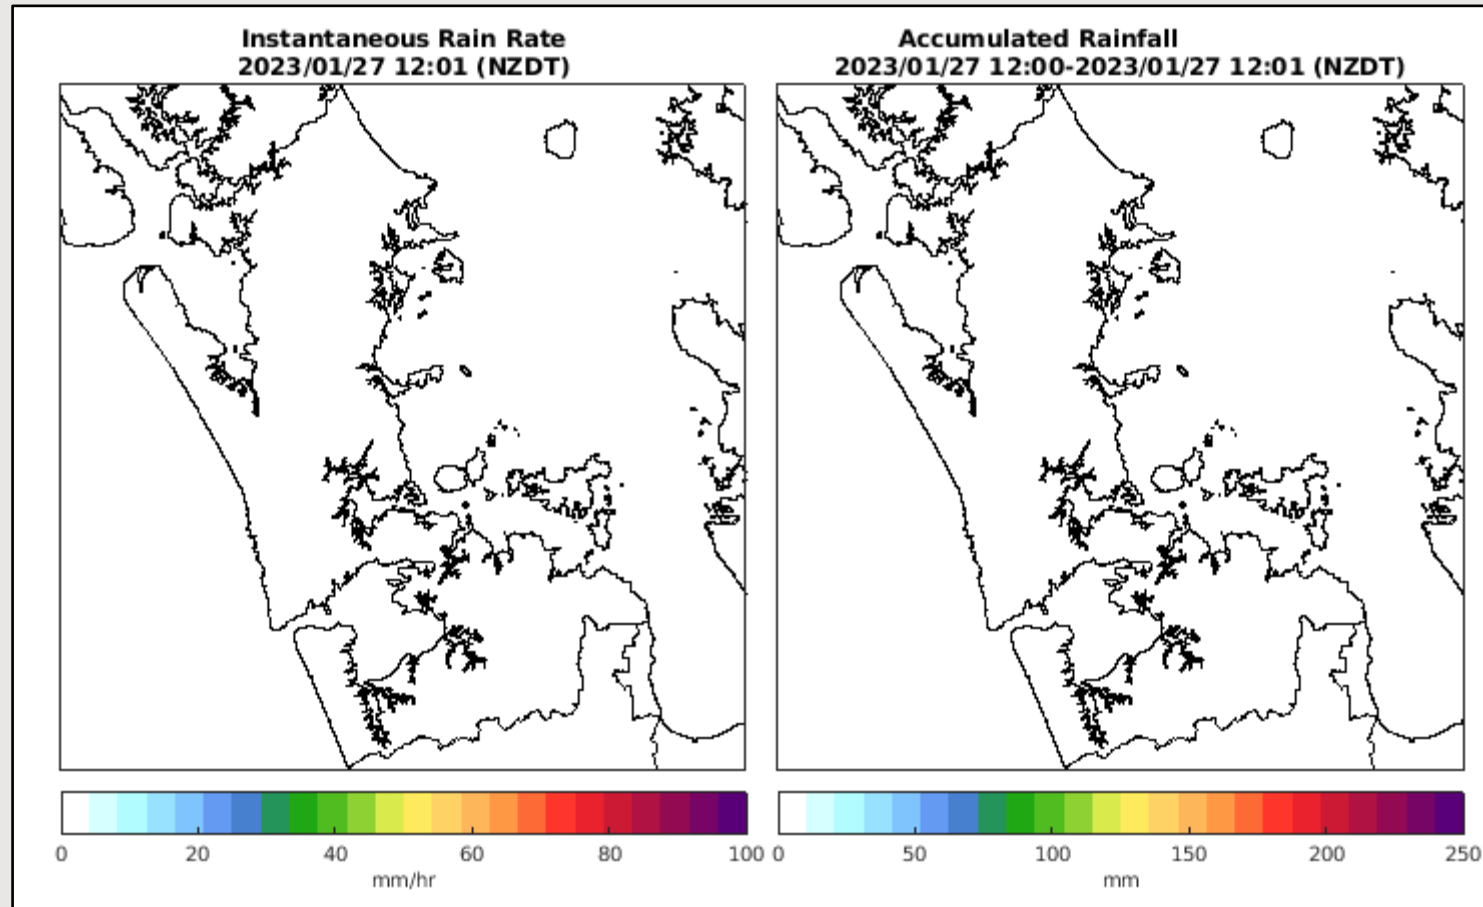

E.G. ENSURING METSERVICE RADAR CALIBRATION

- MetService Calibration wanders around by up to 60% (probably due to technicians changing settings)
- Results in useable rainfall information, everywhere in the Auckland region.

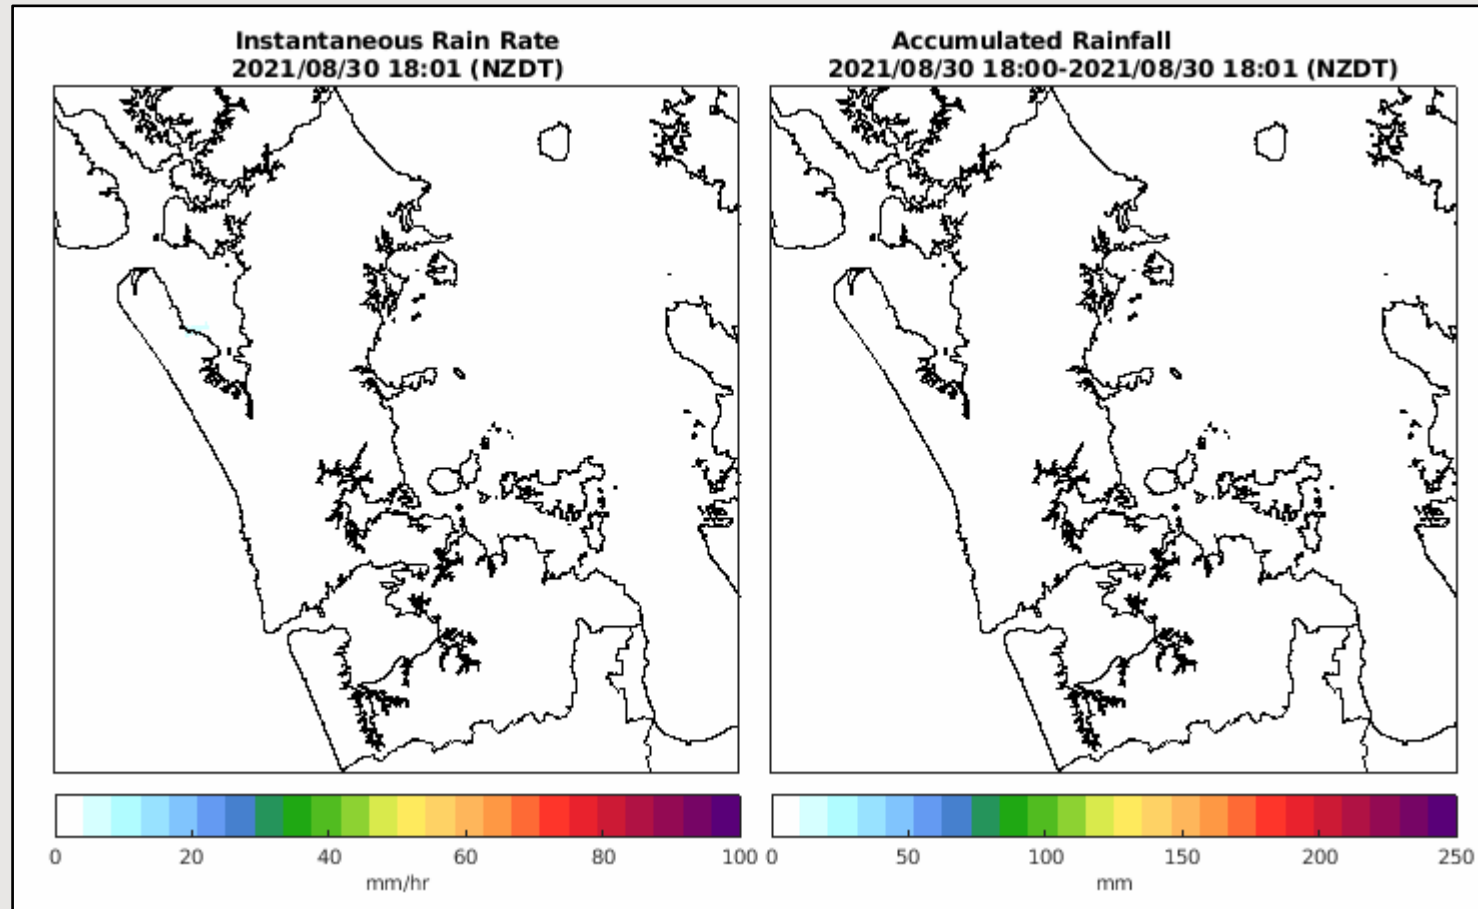

Weather Data systems at Healthy Waters

Observations (Now)

Weather Data systems at Healthy Waters

Observations (Now)

Predictability of the Atmospheric State

after Austin et al 1987

OBSERVATIONS ARE INSUFFICIENT TO MANAGE RISK

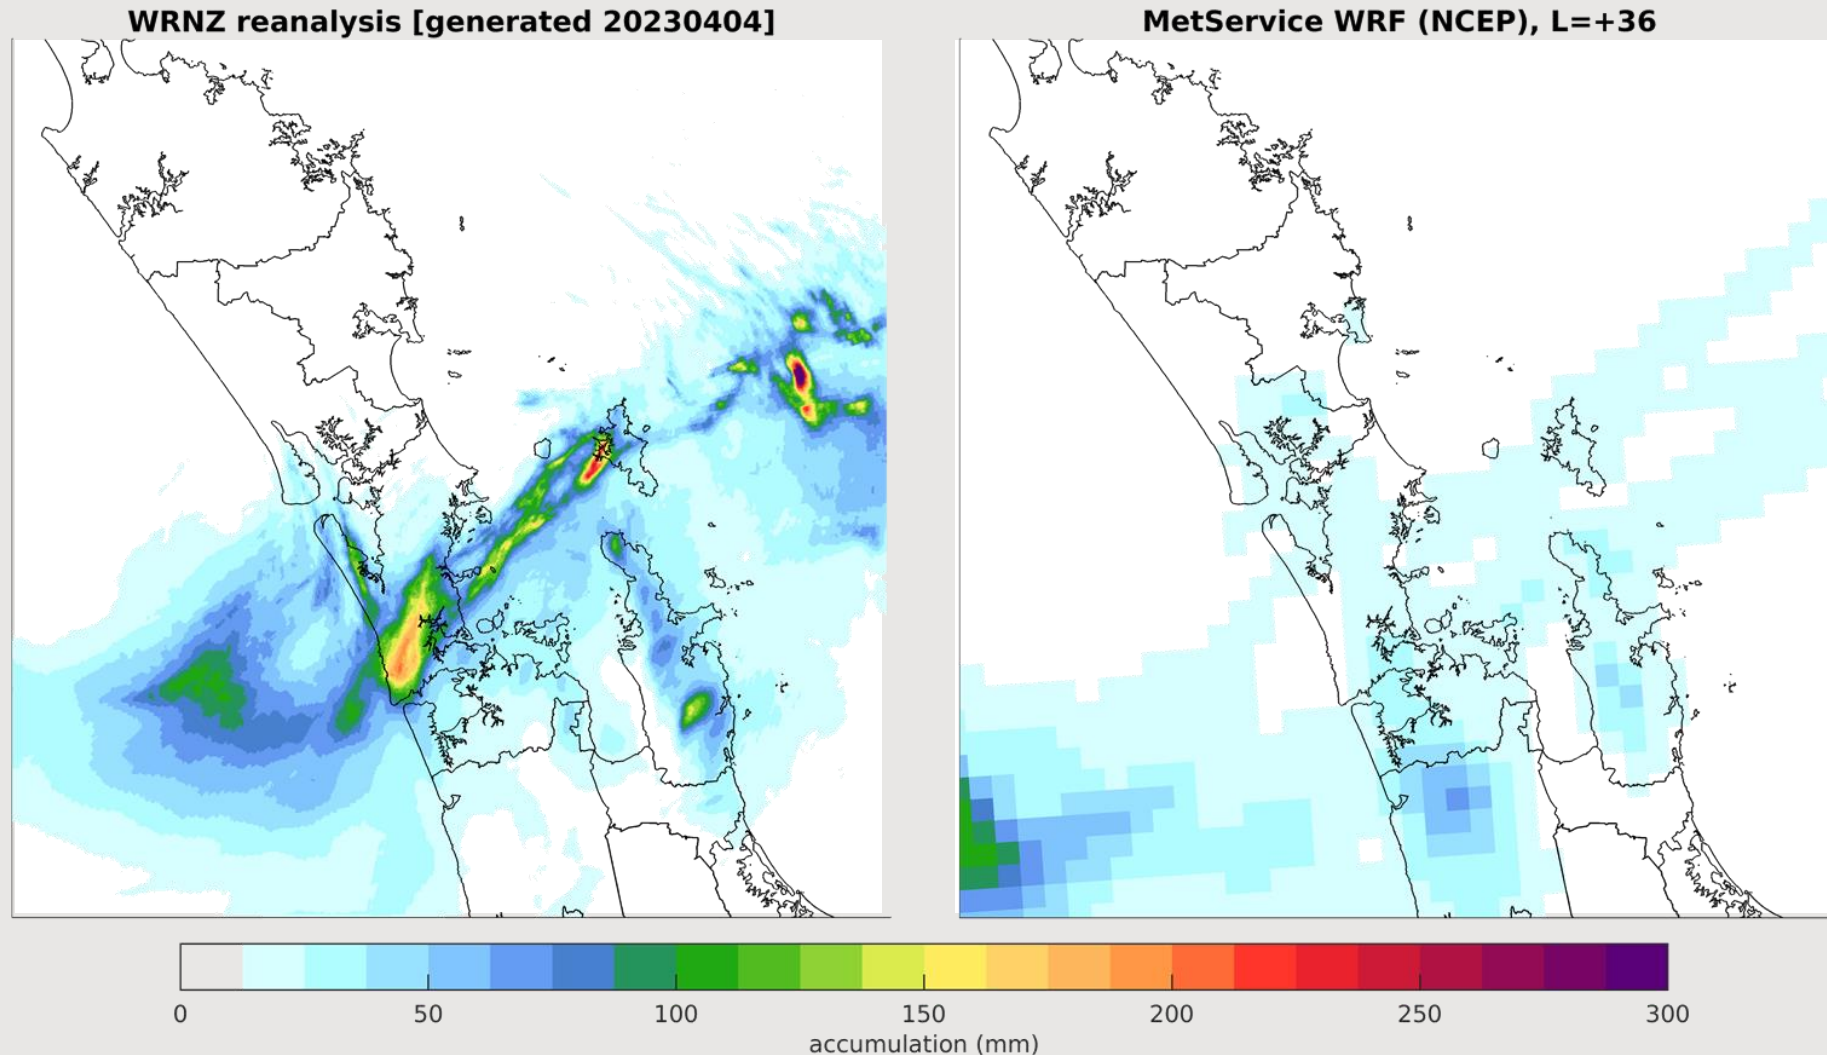

- Probabilistic Forecasting

Weather Data systems at Healthy Waters

NWP Forecasts (Future)

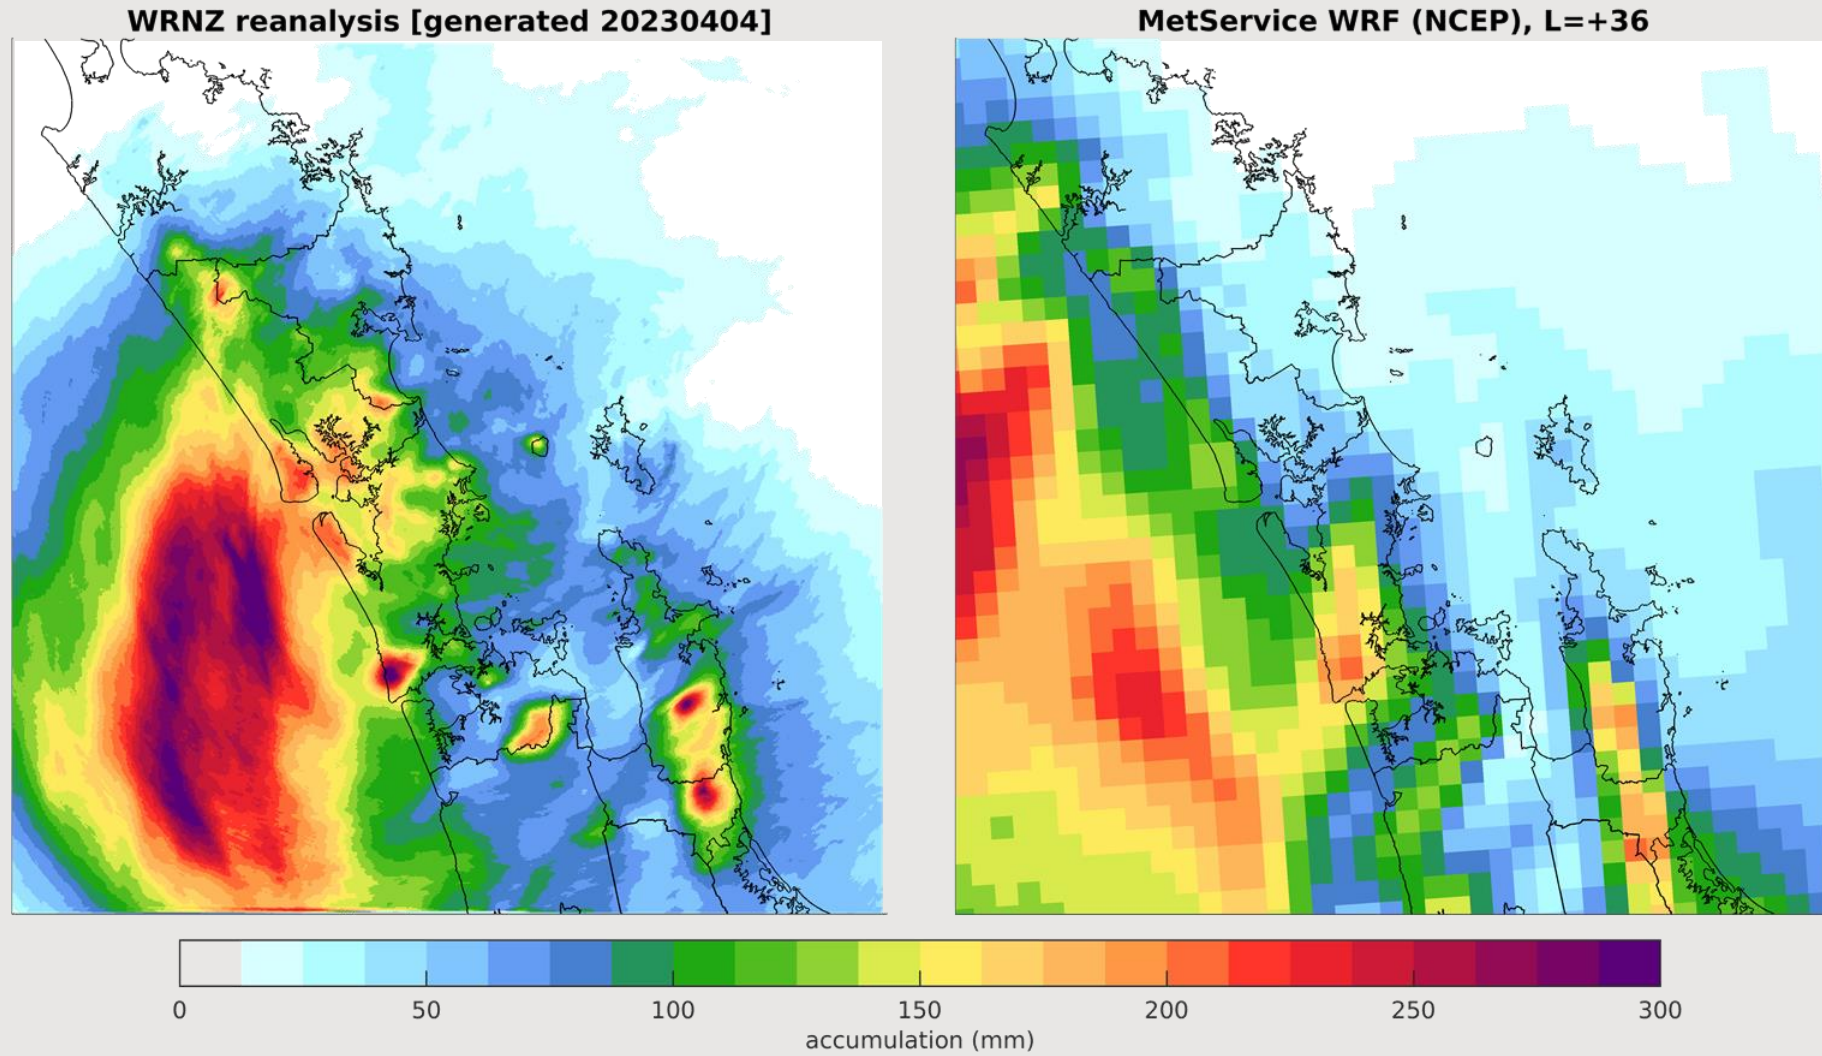

Event total rainfall (2021/08/30 12:00 to 2021/08/31 12:00)

Weather Data systems at Healthy Waters

NWP Forecasts (Future)

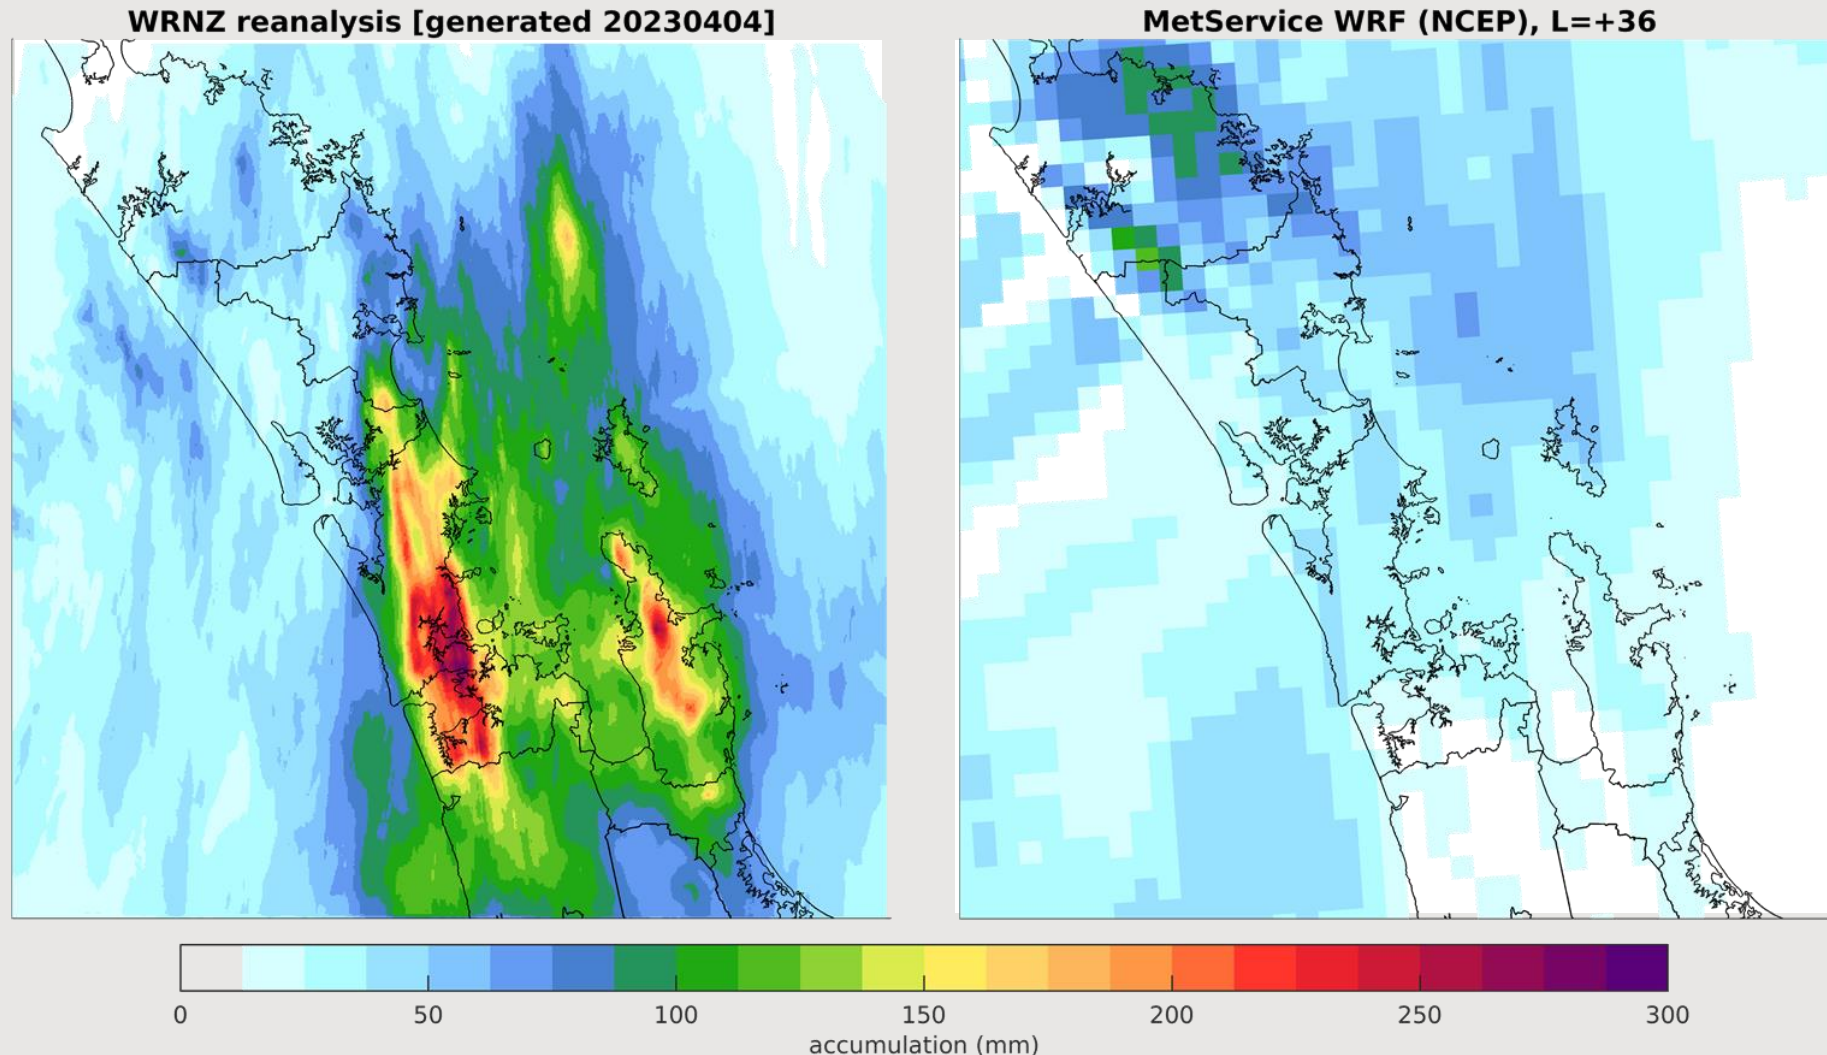

Event total rainfall (2023/02/13 13:00 to 2023/02/14 13:00)

Weather Data systems at Healthy Waters

NWP Forecasts (Future)

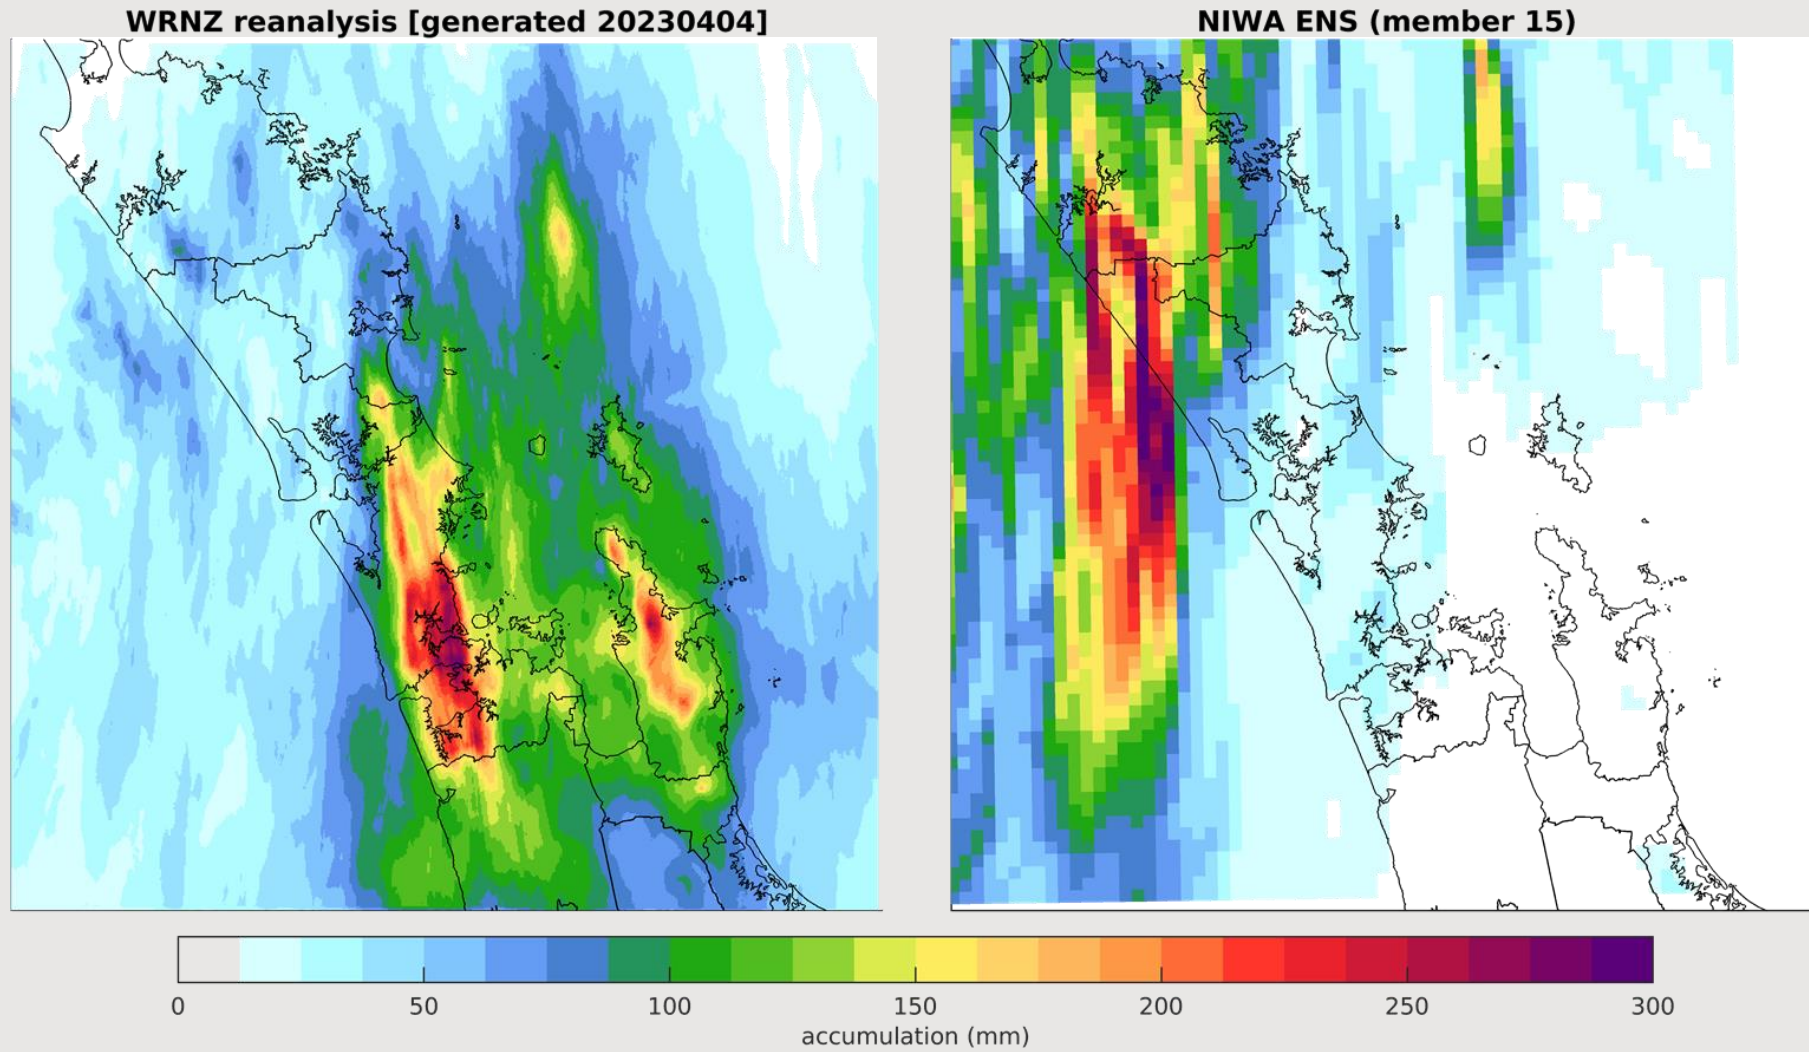

Event total rainfall (2023/01/27 00:00 to 2023/01/28 00:00)

Weather Data systems at Healthy Waters

NWP Forecasts (Future)

Event total rainfall (2023/01/27 00:00 to 2023/01/28 00:00 (NZDT))

Predictability of the Atmospheric State

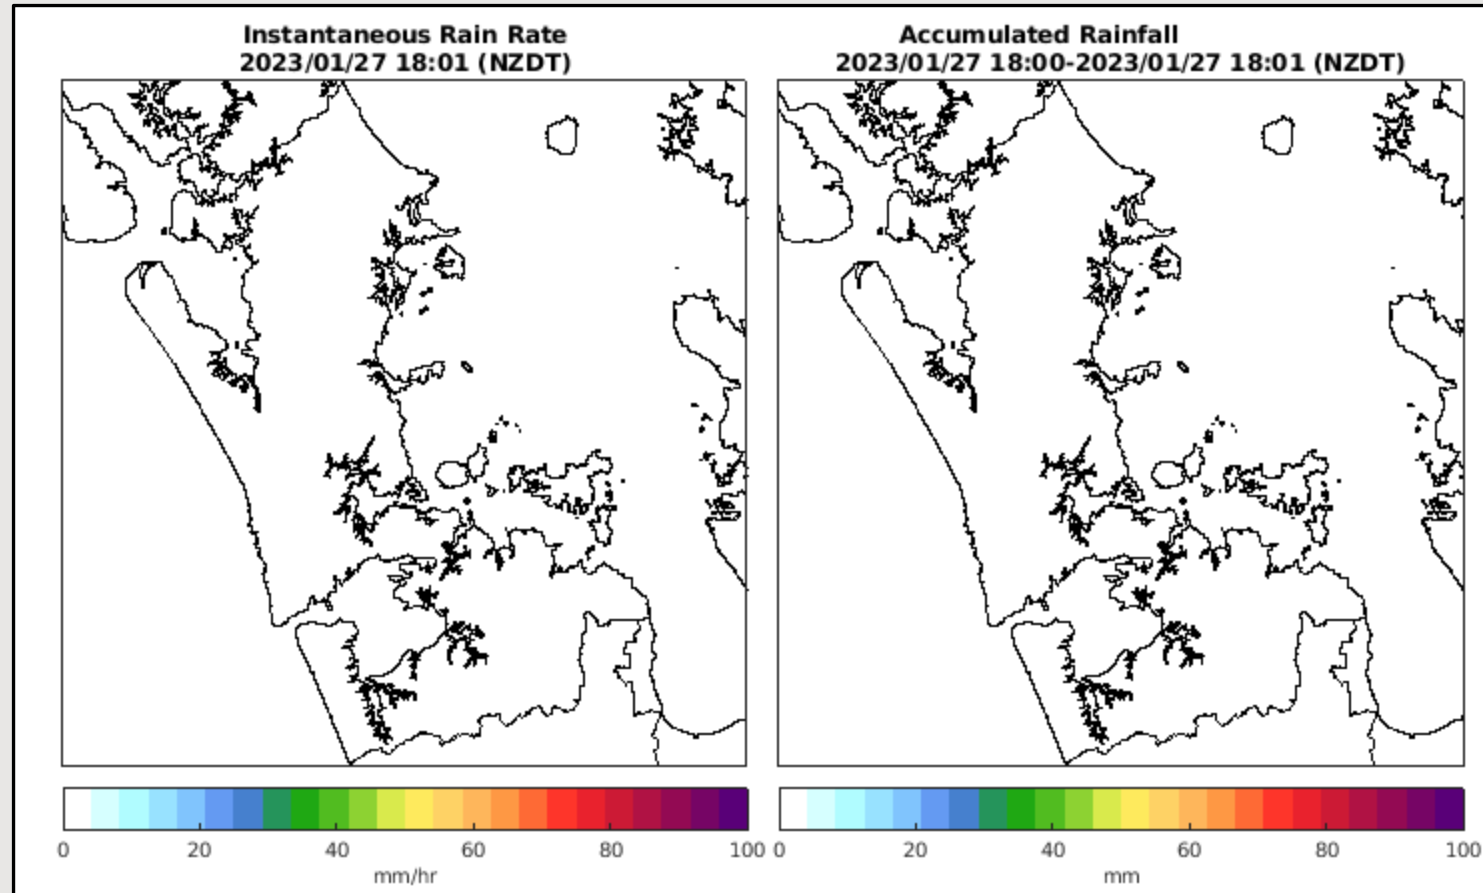

after Austin et al 1987

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours ... often <1!)

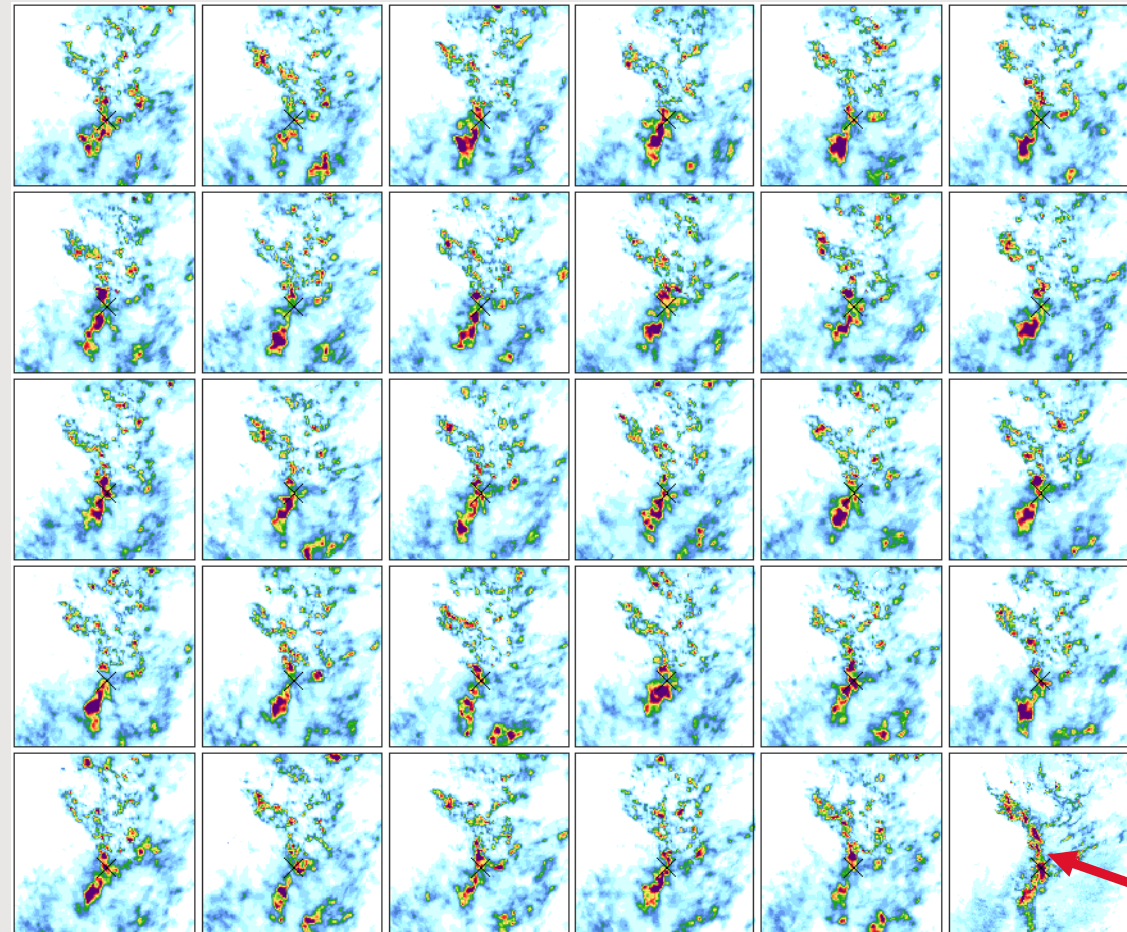

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours)

Based on the observed velocity
(speed/direction) and unpredictability
of the current rain situation.

Same scene as the animation.

15-minute nowcast

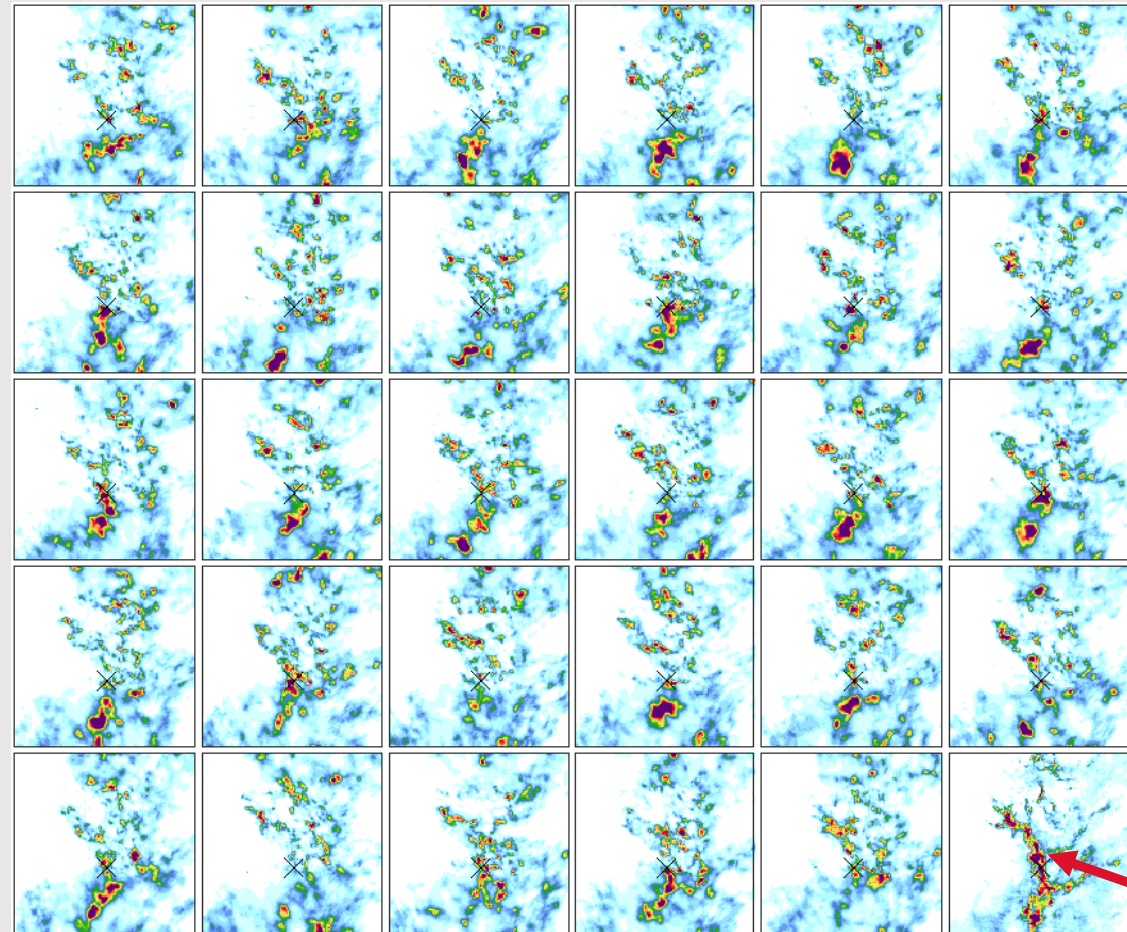

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours)

Based on the observed velocity
(speed/direction) and unpredictability
of the current rain situation.

Same scene as the animation.

30-minute nowcast

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours)

Based on the observed velocity
(speed/direction) and unpredictability
of the current rain situation.

Same scene as the animation.

60-minute nowcast

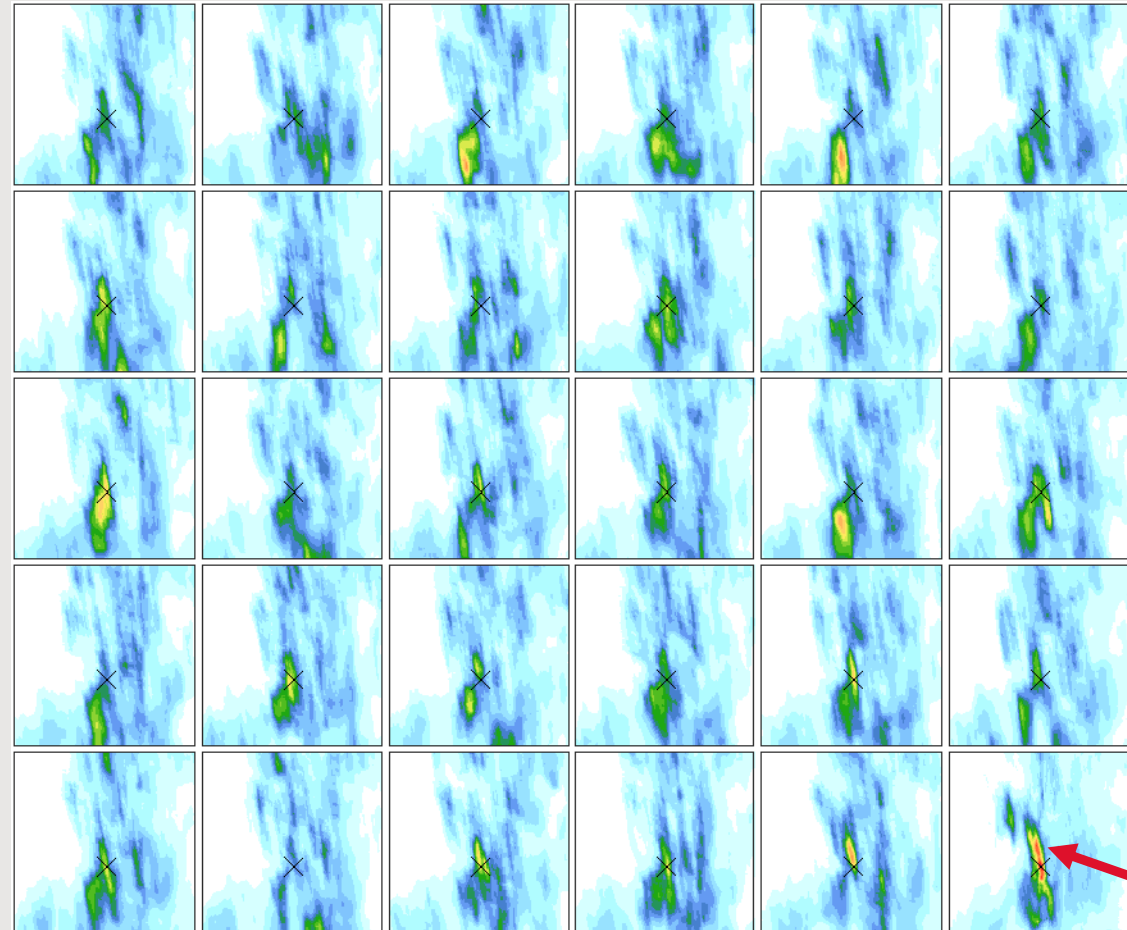

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours)

Based on the observed velocity
(speed/direction) and unpredictability
of the current rain situation.

Same scene as the animation.

60-minute nowcast

Weather Data systems at Healthy Waters

Nowcasting (Leadtime: hours)

27 January 2023: Albert Park Rainfall Nowcast and Observations

Weather Data systems at Healthy Waters

NWP Forecasting (Leadtime: days)

27 January 2023: Albert Park Rainfall Forecast and Observations (MetService, 8km, NCEP)

Predictability of the Atmospheric State

after Austin et al 1987

PROBABILISTIC FORECASTING

- To Quantify Forecast Skill: we need to define the events we are interested in forecasting (Depth, Duration, Frequency, Area)
- Skill is then usefully defined by two statistics: Reliability and Probability of Detection.

PROBABILISTIC FORECASTING

- Reliability: in the long run, do the probabilities issued by the forecasting system match the occurrence frequency of an event.

Above example- probability of the event is $2/3$,

on average, events should occur 66.6% of the time following $p=2/3$ events.

PROBABILISTIC FORECASTING

- Probability of Detection: Given some acceptable probability (or confidence level), what proportion of events can be detected in advance.

Say for taking some action, an acceptable probability (confidence) of an event occurring is $2/3$. For all events, how many were actually preceded by a forecast with a probability of $2/3$ or better?

Reliability and Probability of Detection

Statistics are prepared by tabulating over a 10 year record of radar observations and nowcasts.

Tables are generated for any definition of an event of interest (Depth/Duration/Area) and Leadtime.

Reliability is assessed, then bias correction can be applied. This results in an unbiased estimate of POD(p)

Number of ensemble members >10mm	Nowcast Theoretical Probability	Number of nowcast predicted exceedances	Number of observed exceedances	Observed (Bias corrected) probability	Long term Probability of Detection of an exceedance when alarming at or above this probability	Long Term False Alarm Ratio when alarming at or above this probability
0*	0.00	213434185*	129113	*0.00		
1	0.03	1166202	42057	0.04	0.78	0.86
5	0.17	155365	22439	0.14	0.57	0.67
10	0.33	58064	15669	0.27	0.40	0.52
15	0.50	31035	13408	0.43	0.27	0.39
20	0.67	18379	10729	0.58	0.17	0.29
25	0.83	12210	8877	0.73	0.09	0.20
30	1.00	9612	8755	0.91	0.01	0.09

TABLES.

DDA = Depth/Duration/ Area Covered, W.a. =
localization of the event e.g. somewhere in 32x32km

Probability =
(bias corrected)
fraction of
ensemble
members in
agreement an
event is going to
occur. Can be
thought of as
confidence an
event will
happen.

Event not
predictable at
this level of
localisation

POD =
Probability of
Detection
(fraction of
events of this
size detected in
advance)

How long in the
future

WEATHER DATA

Should have a probability attached to it.

**WEATHER DATA
TYPES**

Will be able to be compared
for
“Reliability”
AND
“Probability of Detection”

ENGINEERS

Deterministic
modelling doesn't
work for extreme
events

GOOD NEWS

Deterministic models
can be run
probabilistically.

Predictability of the Atmospheric State
